ABSTRACT

The traditional dynamic analysis of the structures has accomplished on the fixed-base models. In general, the response of structures subjected to earthquake excitations are involved by three main components: structure, foundation, and the soil site layers. Seismic analysis of structural systems with the fixed-base model is suitable for structures built on the bedrock. If the structure has constructed on soft soil, both the control algorithm and the structural system shall include the Soil-Structure Interaction (SSI) that covers the flexibility of the soil and the displacement of the foundation. This leads to an increase in the number of the system's degrees of freedom that is changes the structural response behavior and accordingly control actions. This paper used a new type of hybrid control, combining passive and active systems, the Hybrid Damper-Actuator Bracing Control (HDABC), that is an effective protection system. In the structures which used the closed-loop control system whose utilities by Linear Quadratic Regulator (LQR) techniques to identify the structure with hybrid control. In this study, the effects of SSI on the seismic response of the steel structures under strong earthquakes who has built on shallow foundation and supplied with HDABC system, as energy absorber elements has been investigated. For this purpose, the moment resistant steel frames are considered and the time history analysis of them has treated on the structural models with either considering the SSI or without. The smart structure modeling and control design is carried out using MATLAB software in the state space form. The substructuring method achieved from SSI software such as SASSI2000 has used to evaluate the SSI dynamic response. Based on the analysis response, they are shown in the SSI cases, control forces result are more reduced of the structural response than without SSI. The control forces sequence in without SSI are smaller than with SSI case and SSI is effective for the hybrid control, needs to be included in the design of hybrid system as well as other types of the control for buildings on soft soil.

INTRODUCTION

Structural control is a relatively new technology for building protection under a severe environmental disturbance such as strong winds or earthquakes. These systems have categorized such as active, passive, hybrid and semi-active controls. The passive control technique including base isolation is the earliest and most widely used application for its simplicity, and it does not require an external power. The active control

SEE 7

system put control forces on the building structure through employment of actuators with external power input, which may exclude the inelastic deformation for considered earthquakes. The hybrid control system combines the passive and active control devices to reduce the input power required by the active system (Cheng et al., 2008). A hybrid control system has utilized in this paper. The system is composed of visco elastic dampers and hydraulic actuators mounted on a chevron brace between adjacent floors, called hybrid actuator-damper-bracing control (HDABC) it is shown in figure 1.

Figure 1. One-story structure with HDABC system

It has recognized suitably that the seismic response of a structure could be influenced by its supporting conditions such as fixed base and soil–structure interaction (SSI). Considering SSI in structural control to evaluate the effects of SSI on the response of structures with the control design based on the fixed base assumptions (Zhang et al., 2006, Wolf, 1985). There are two kinds of SSI interactions: Inertial and kinematic. Inertial interaction refers to displacements and rotations at the foundation level of a structure that result from inertia-driven forces such as base shear and moment. Kinematic interaction results from the presence of stiff foundation elements on or in soil, which causes motions at the foundation to deviate from free-field motions, which describes the ground motion at site without existence of a structure (NEHRP SSI for building structures, 2012). The inertial interaction is more significant than the kinematic interaction for the case of foundation without huge, rigid base slab or deep embedment. The inertial interaction has therefore considered in this study with the impedance function to model the soil–foundation dynamic characteristics. <p>\n It is to use that the seismic response of a structure could be infinitely that the science by its supporting SSD. Considering SSD. Considering SSD is structured in the response of structures with the control design based on the fixed base SLO. Notice in certain and action refers to displacements: and rotations to SSD in the error to this of SSD in the error. In particular, and, we can see that, if the reference system is not possible to represent the same information. The increase of a structure that forces such as base shear and moment. Kinematic interaction results from the elements on or in soil, which causes motions in the foundation of derivatives, the ground motion at site without existence of a structure (NEHR PSS) D12. The inertial interaction is more significant than the kinematic interaction for without huge, rigid base slab or deep embeddingment. The inertia interaction has this study with the impedance function to model the soil–foundation dynamic this study with the impedance function to model the soil–foundation dynamic system pluons (Znang et al., 2000, Wolt, 1955). Inter are two kinds or S

idic. Inertial interaction refers to displacements and rotations at the found

from inertia-driven forces such as base shear and moment. Kinematic

ce of *xlang* et al., 2000, wor, 1950.) The are two knots of some measons: mental interaction refers to displacements and rotations at the foundation level of a structure that the divinal interaction refers to displacements fan

DEFINITION OF THE HYBRID CONTROL SYSTEM (HDABC)

The motion equations for an *n*-story shear building structure equipped with a hybrid control device under a horizontal earthquake acceleration input can derived (Spencer and Chang, 2013; Cheng et al., 2008) as:

$$
[M]\{\ddot{x}\} + [C]\{\dot{x}\} + [K]\{\dot{x}\} = [u_a]\{f_a\} + [u_p]\{f_p\} + \{u_r\}\ddot{x}_s
$$
 (1)

Where $\{x\} = [x_1, x_2, \dots, x_n; x_{b_1}, x_{b_2}, \dots, x_{b_m}]^T$ is the vector of floor and bracing displacements are denoted by x_1 and x_2 , respectively; $[M]$, $[C]$ and $[K]$ are mass, damping and stiffness matrices, respectively; $[u_a]$, result from inertia-driven forces such as base shear and moment. Kinem

presence of stiff foundation dements on or in soil, which causes motions at the foundation to deviate from
fr for earthquake ground acceleration inputs, \dot{x}_s , respectively. $\{I_n\}$ is unit vector in order of *n*. As shown in Fig. 1, the hybrid control system is composed of visco-elastic dampers as the passive part and hydraulic actuators system as the active part. Cylinders of the damper and actuator have connected to a structural floor and the piston bar of both damper and actuator have connected to the Chevron-brace. The displacement

$$
J = \int_{0}^{\infty} \left(\left\{ Z(t) \right\}^{T} \left[Q \right] \left\{ Z(t) \right\} + \left\{ u(t) \right\}^{T} \left[R \right] \left\{ u(t) \right\} \right) dt \tag{11}
$$

Where [Q], [R] are weighing matrices. Magnitudes of [Q], [R] represent the relative importance to the structural response and to the control forces. This influence has decided by the ratio of two matrix magnitudes. The assignment of larger values for elements in [Q] relative to those in [R] indicates the response reduction is given priority over the control force and larger control forces will be generated to cause more response reduction. The gain matrix $[G]$ can obtained by solution of Riccati equation given by:

$$
[P][A] + [A]^T [P] - [P][B_u][R]^{-1} [P] + [Q] = 0 \tag{12}
$$

$$
\left[G\right] = \left[R\right]^{-1} \left[B_u\right]^{T} \left[P\right] \tag{13}
$$

Where $[P]$ is the Riccati matrix (Ghaffarzadeh and Younespour, 2014).

INVOLVING THE SSI ON THE CONTROL STRATEGIES

For the inertia interaction formulation, the foundation–soil interaction stiffness and damping characteristics have quantified by the impedance function, which provides a frequency dependent stiffness damping model (Wolf, 1985). In the time domain analysis, the model has simplified as a set of frequency independent springs and dashpots. Their stiffness, K_s , and damping coefficients, C_s have taken from the corresponding impedance function items at the fundamental frequency of the SSI system (Amini and Shadlou, 2011; NEHRP SSI for building structures, 2012). The motion equation for the hybrid controlled SSI system (an n-story shear building) under the input of ground horizontal accelerations, \ddot{x} as shown in Figure 2, can written (Zhang et al., 2006) as: $[P][A]+[A]^T[P]-[P][B_+][R]^+[P]+[Q]=0$ (12)
 $[G]=[R]^+[B_+]^T[P]$ (13)

iccati matrix (Ghaffarzadeh and Younespour, 2014).

The number of braces, *m* can b an identify matrix with order of two. The floor displacements \int_0^T with $\{x_i(t)\} = \{x(t)\} + [\Gamma]\{X_f(t)\}$, where $\{x(t)\}$ is to the foundation and $\{X_f(t)\} = [x$ simple building-foundation systems, so there is I_0 rather than I_7 in this model. The input

rices in Eq. (14) has expressed as:
 $\begin{bmatrix} u'_a \end{bmatrix} = -\begin{bmatrix} -u_a \end{bmatrix}, \quad [u'_a] = -\begin{bmatrix} -u_g \end{bmatrix}, \quad [u'_a] = -\begin{bmatrix} M_{331} \end{bmatrix} \begin$ $\left[u_x^2\right] = \left[\frac{u_x}{r^4 u_x}\right]$, $\left[u_y^2\right] = -\left[\frac{u_y}{r^4 u_y}\right]$, $\left[u_y$

NUMERICAL STUDY ON THE RESPONSE OF MODELS

A six-story building has utilized in this study with all parameters for the structural model, hybrid system model, foundation and soil. Table 1 summarizes all the parameters:

		Table 1. System parameters for numerical examples	
model	parameter	value	unit
structure	Floor mass M_s	110	ton
	Brace mass M_h	0.75	ton
	Column stiffness k_s	$k_1 = 3.51e5$, $k_2 = 2.25e5$, $k_3 = 1.7e5$ $k_4 = 1.24e5$, $k_5 = 8.8e4$, $k_6 = 6e4$	KN/m
	Brace stiffness k_b	2×10^5	KN/m
	Story height h	3.75	m
Hydraulic Actuator	Fluid Bulk modulus S	6.9033×10^{5}	$\frac{KN}{m^2}$
	Supply pressure P_s	2.071×10^{4}	$\frac{KN}{m^2}$
	Frequency bandwidth f_b	53.63	$\rm Hz$
Passive Damper	Damper coefficient C_0	3500	$\frac{KN}{m^2}$
	Relaxation time $\}$ ₀	0.05	\blacksquare
Foundation	Half side length	7	m
	Mass m_0	220	ton
	Moment of inertia I_0	300	$\tan.m^2$
Soil	Mass density \ldots	1700	$\frac{kg}{m^3}$

Table 1. System parameters for numerical examples

$$
k_{HH} = 1.5e9 \text{ N/m}; \quad k_{MM} = 5.6e10N; \quad c_{HH} = 4e7N \text{ s/m}; \quad c_{MM} = 1.3e8N \text{ s}
$$
 (17)

In this paper, the Kobe (1995) earthquake ground motion has used for the dynamic time history analysis of these models. The controlled and uncontrolled roof displacement and acceleration time responses have shown as bellow:

Figure 4. Comparison of response time history of 6th floor, HDABC system without SSI considered

Figure 5. Comparison of response time history of 6th floor, HDABC system with SSI considered

Figure 6. Comparison of acceleration of $6th$ floor, HDABC system without SSI considered

Figure 7. Comparison of acceleration of 6th floor, HDABC system with SSI considered

CONCLUSION

Dynamic soil-structure interaction under earthquake loads is a complicated phenomenon. Unless the fundamental frequency of the structure is near that of its supporting soil strata, SSI generally results in a reduction of the structural deformation and shear force at base. In this study, it has shown that assuming fixed-base for a structure with shallow foundation is not conservative. This study has focused on the evaluation of LQR controller considering Soil-Structure Interaction effects. It has shown that the applied system identification in this study is useful for other analyses of structure considering SSI effects. They have shown in the SSI cases, control forces result have more reduced of the structural response than without SSI. The result shows that the reduction of SSI-controlled model is about 66 percent of peak response. In addition, as the acceleration response of SSI-controlled model is about 69 percent of peak response reduction calculated. On the other hand as shown as results has seen that the control effort of HDABC devices is 118 percent is more economical to suppress the lateral displacement of the structural model in this research.
